

RANGE ANALYSIS SUMMARY MONTGOMERY PASS WILDHORSE TERRITORY

The Montgomery Pass Wild Horse Territory (MPWHT) was analyzed in the fall of 1986 for various range analysis data. It is a remote area that up until now, has received little in the way of research. This includes comprehensive mapping, aerial photography, range analysis and soil inventory. The main objective of this study was to assess its grazing capacity as summer range for wild horses. The vegetation and soil of the key areas of the territory were examined for type, condition and trend, forage availability and grazing capacity.

The MPWHT is located east of Mono Lake in the southern portion of the Excelsior Mountains. It is bounded on the northwest by Hwy. 167 and to the southeast by the White Mountain Range from Bishop to Montgomery Pass. The elevation is approximately 7100 feet

Analysis, as described in the Forest Service Handbook (FSH 2209.21 R-4), includes the following: 1) delineation of vegetative types on aerial photographs, 2) inventory of vegetation within each type, 3) vegetative and soil condition and apparent trend determinations and 4) collection of soil information in each vegetation type.

METHOD S

Mapping of vegetation types was done in the field on aerial photographs on the basis of the dominant vegetation on the site. The vegetation types found on the MPWHT are as follows:

- 2D Dry Meadows characterized by grasses and seasonally wet soil
- 2W Wet Meadows characterized by sedges and constantly wet soil
- 4T Tall Sagebrush typically Artemisia tridentata tridentata
- 4L Low Sagebrush includes Artemisia arbuscula and Artemisia nova
- 4R Rabbitbrush Chrysothamnus spp.
- 5 Browse-Shrub includes willow (Salix spp.)
- 8 Barren areas of sparse or absent vegetation
- 9 Pinyon-Juniper pure or mixed stands
- 16 Desert Shrub includes Menodora spinescens in the MPWHT

20(4T) - Cultural Treatment Area - areas previously burned and revegetating as tall sagebrush

The type symbols with the corresponding condition and trend symbols and acreage for each vegetation type were recorded on the photos.

Vegetative inventory information was obtained with data collected on the Site Analysis form R4-2200-13 (Appendix 1) and the Ocular Analysis Form R4-2200-10 (Appendix 2). Each anyalysis was given a write-up number which corresponds to the recorder's last initial and the number of the analysis. Site analyses are a plot-by-plot check of plant composition, vegetative production, percent cover of vegetation, litter and bare ground. Each site analysis consisted of ten

late 86

circular plots evenly spaced in a representative area of each vegetation type. The plot size is determined by the vegetation type. The sagebrush type is measured with a 9.6 sq. ft. hoop and the meadow types, a .96 sq. ft. hoop. The vegetation in the hoop was clipped off and weighed in grams with a hand-held scale. The grams measured were converted to pounds per acre using a mathematical formula created in conjunction with the plot sizes and numbers. Total vegetation present at the plot was determined by estimating the amount of forage consumed by animals and adding it to the amount of forage remaining in the plot.

A vegetation condition rating was given for each site analysis and transect run. The rating is based on a scale of 0 - 100 and consists of points given for composition and production. Composition accounts for 60% of the condition rating and is determined by the ratios of "desirable", "intermediate" and "least desirable" plant species occurring in the stand. The production rating accounts for the remaining 40% of the condition rating and is the quotient of the pounds per acre of preferred forage and the total estimated forage production potential of the site.

In addition to vegetation information, soil condition parameters were also measured. The percent cover of bare soil, pavement, rock and litter is determined. The slope of the terrain, the soil's permeability and current signs of erosion contribute to the soil condition rating. This was based again on a scale of 0 to 100. Fifty percent of the score is based on the percent of ground cover from vegetation, pavement and rock, and the remaining 50% was based on the current erosion index which accounts for soil movement due to water and wind. Adjustments in the soil condition ratings are made for areas of low rainfall, ie: low sagebrush and pinyon-juniper types.

Condition ratings for vegetation and soil are interpreted as follows:

81 - 100 Excellent 61 - 80 Good 41 - 60 Fair 21 - 40 Poor 0 - 20 Very Poor

Droppings of cows, sheep, deer and horses were also recorded at each plot. All droppings, old or new, were recorded if found within an 11.7 foot radius of the center of each plot. From these data, relative use can be determined for each class of animal.

The Ocular Analysis was used in vegetation types that are similar to previously analyzed vegetation types. It is a simplified form that uses estimated percent composition for the plant species present. The total weights of plant production were estimated on the actual amounts found in site analyses done in the same vegetation types. Vegetative condition and soil condition ratings were obtained as described above for the site analysis form. A minimum of one site analysis and one soil type inventory must be done for each two ocular analyses.

Apparent Trend in soil stability and vegetation was judged separately for each area on which condition has been determined. This was done with Apparent Range Trend form R4-2200-25 (Appendix 3). The vegetation was rated on plant vigor relative to plants growing in similar locations, frequency of "desirable" and "intermediate" plants, distribution of age classes of favorable plants and the effects of grazing and/or trampling of plants by grazing animals. The soil was rated on ground cover dispersion (%), soil movement (light, moderate, etc.) and the presence or absence of wind or water-caused erosion. Apparent trend is a judgement based on soil and vegetative indicators observed while conducting the analysis and should not be confused with long-term trend ratings. Long-term trend is determined from repeated measurements on permanent benchmarks which is much more reliable than a one-time observation. Apparent trend ratings for vegetation are displayed as follows: \uparrow upward, \checkmark downward, \rightarrow no apparent trend or stable.

The vegetative condition rating and the soil condition rating were recorded along with the trend indicators next to the vegetation type symbol. They were recorded as the quotient of the two scores with the vegetation on top and soil on the bottom. For example, 4T $55^{1/80}$; is a tall sagebrush type, the vegetation condition is fair and its trend is upward, the soil condition is good and its trend is stable.

An intensive soil inventory was done at each site analysis and sent to the Soil Conservation Service for taxonomic identification (Appendix 4). At the transect site, soil pits were dug to a depth of 40 inches or until a hardpan was reached. The soil horizons were identified by depth, texture, color, pH and permeability. The topographic location, percent slope, aspect and parent material were also noted. The comprehensive soil determinations are useful in determining vegetation information which is related to the soil type. For example, estimated forage production is directly related to the soil type.

The summary process involves the compilation of the data collected on the Tentative Grazing Capacity form R4-2200-24 (Appendix 5). Each analysis is listed by write-up number, vegetation type, number of acres per type and pounds per acre of forage plants produced in each type. The grazing capacity in days is determined by applying calculations as shown on the form, using figures found in the Range Analysis Handbook, 1981. The assumptions used from the handbook are as follows:

Dry Weight Allowance - 19 or 26 lbs forage/horse/day Proper Use of Key Species - 35% to 55%, dependent on range type and condition Utilization of Total Palatable Plants - 18% to 32%, dependent on proper use of key species.

RESULTS

A total of 39,453 acres were surveyed in the MPWHT. Approximately 1,588 acres were considered barren and/or unproductive (Type 8) and were, therefore, considered unsuitable. The remaining 37,865 acres of suitable habitat produce a range of 13 to 410 pounds of forage per acre.

There are several variables to consider when evaluating the data for tentative grazing capacity. It must be understood that tentative grazing capacity involves a mathematical calculation based on the pounds of usable forage growing on the suitable, primary range and that there are many variables which can affect the accuracy of this method. Some of these variables include the delineation of the primary range, pounds of forage produced on the primary range, proper use criteria, and the pounds of forage consumed per animal month by the various classes and species of animals using the area. Several examples of varied interpretations are shown below.

1. Of the suitable acreage, 15,927 acres were used for calculating tentative grazing capacity. The additional 21,938 acres were not included in the calculations for tentative grazing capacity because they were producing less than 50 pounds of dry weight forage per acre at the time. There is a total of of 811,798 pounds of forage available, assuming that the horses will utilize 25% of the available sagebrush. Given that a horse uses 26 pounds of forage per day, there are 31,223 horse days available. Assuming 30 days per month and use 6 months out of the year, the figures indicate a tentative grazing capacity of 173 horses for 6 months out of the year on the key summer range (Table 1).

2. Horse days were calculated on the basis of acreage producing more than 50 pounds per acre of forage, assuming that no sagebrush is used by the horses for forage and that each horse needs 26 pounds of forage per day. This yielded 17,348 horse days, 578 horse months and 96 horses for 6 months of the year.

3. Using acreage included only in the southern part of the Key Range Area, there were 13,359 acres of suitable habitat. Since the Key Range is concentrated around known watering spots, acreage producing less than 50 pounds of forage per acre were included in these calculations. It was also assumed that no sagebrush was used in these areas. These assumptions yield 12,358 horse days, 412 horse months and 68 horsess for 6 months of the year.

4. The northern and southern parts of the Key Range Area account for 16,618 acres of the study area. Of this, 11,199 acres are producing more than 50 lbs of forage per acre (Table 2). The values applied for proper use of key species and the utilization of total palatable plants were determined on the basis of vegetation type and range condition as shown below.

Proper Use of Key Species:

	Rang	<u>e Conditio</u>	<u>n</u>
Vegetation Type	good	fair	poor
2D, 2W (Meadows)	55%	45%	35%
4T, 4L, 4R (Sagebrush)	45%	40%	35%

Utilization of Total Palatable Plants:

Proper Use (%) 35....18% 40....21% 45....24% 55....32%

Assuming that the horses eat no sagebrush and that each animal consumes 26 lbs of forage per day, this area will support 14,273 horse days or 80 horses for 6 months of the year.

These mathematical indications are examples of interpretations that are possible with the given data. It should be realized that these are estimates only and follow-up studies are necessary in order to verify the carrying

•	Favorable frequency grouping and age classes of desirables, intermediates, and least desirables.	den strengten gena	1.	A disproportionate amount of intermediates and least desira- bles. Seedlings of better plants having difficulty in becoming established.
•	Forage plants not being pulled up or trampled out by grazing.		2.	Forage species being pulled up and trampled out by grazing.
	Vigor of key species high as indicated by leaf length, seed stock production, and normal color.	<u>/</u>	3.	Low vigor of key species as indi- cated by reduced size of plant, reduced leaf length, lack of seed stalks, and off color (sickly yellow).
•	Browse species showing little or no hedging.		4.	Browse species showing heavy hedging.
	Up or Stable	5	SOIL	Down
•	Ground cover dispersion - uniform.	\checkmark	1.	Ground cover dispersion - vari- able to highly variable.
•	No detectable soil movement.		2.	Soil movement detectable.
•	Soil cover continuous and intact.	1	3.	Soil Cover broken and soil exposed.
•	No exposure of plant roots.		4.	Plant roots exposed. 1/
•	Stones and rock fragments where present, normal, and in place - no movement of rock fragments.	1	5.	Stones and rock fragments, where present, concentrating on surface as erosion pavement. Fragments loose and often moving downslope
•	Lichen lines on stones and rock fragments extend to soil level.		6.	Lichen lines on stones consider- ably above soil surface - no lichens on rock fragments.
• .	No active gullies.	<u>.</u>	7.	Active gullies - indicated by recent cutting and sloughing.
•	No recent soil deposits either alluvial or aeolian.		8.	Recent soil deposits - alluvial or aeolian.
	No wind-scoured depressions.		9.	Wind-scoured depressions.

TOTAL									

* Cow or sheep (fill in the class of livestock that applies) days per acre is determined by dividing the usable forage per acre toolium: E) by the daily dry weight constitution of the animals involved.

** Fill in the kind of livestock in blank space provided.
